## Example of picture abstraction

## Example of picture abstraction

Abstractions of a man / crowd

Fingerprint

Eye color度

DNA

Individual heights

## Numerical abstractions used in Astrée

Collecting semantics: partial traces

Octagons:
$\pm \mathrm{x} \pm \mathrm{y} \leqslant a$

Intervals.

$$
\mathbf{x} \in[a, b]
$$

Ellipses.
$\mathrm{x}^{2}+b \mathrm{y}^{2}-a \mathrm{xy} \leqslant d$

Simple congruences:

$$
\mathbf{x} \equiv a[b]
$$

Exponentials:

$$
-a^{b t} \leqslant \mathrm{y}(t) \leqslant a^{b t}
$$

## Numerical abstractions used in Astrée

 typedef enum \{FALSE $=0$, TRUE $=1\}$ BOOLEAN; BOOLEAN INIT; float P, X; void filter () \{static float E[2], S[2];

Ellipsoids $(x-a)^{2}+(y-b)^{2} \leq c \quad[F e r 05 b]$
if (INIT) $\{\mathrm{S}[0]=\mathrm{X} ; \mathrm{P}=\mathrm{X} ; \mathrm{E}[0]=\mathrm{X} ;\}$
else $\{P=((((0.5 * X)-(E[0] * 0.7))+(E[1] * 0.4))$ $+(S[0] * 1.5))-(S[1] * 0.7)) ;\}$
$E[1]=E[0] ; E[0]=X ; S[1]=S[0] ; S[0]=P$;
/* S[0], S[1] in [-1327.02698354, 1327.02698354] */
\}

$$
\text { void main () \{ } \mathrm{X}=0.2 * \mathrm{X}+5 \text {; INIT = TRUE; }
$$

while (1) \{
$\mathrm{X}=0.9 * \mathrm{X}+35 ; / *$ simulated filter input */
filter (); INIT = FALSE; \}

## Numerical abstractions used in Astrée

```
% cat retro.c
typedef enum {FALSE=0, TRUE=1} BOOL;
BOOL FIRST;
volatile BOOL SWITCH;
volatile float E;
float P, X, A, B;
void dev( )
{ X=E;
    if (FIRST) { P = X; }
    else
    if (SWITCH) {A = P;}
```

    void main()
    \{ FIRST = TRUE;
    while (TRUE) \{
        \(\operatorname{dev}() ;\)
        FIRST = FALSE;
        __ASTREE_wait_for_clock(());
    \}\}
    \% cat retro.config
__ASTREE_volatile_input((E [-15.0, 15.0]));
__ASTREE_volatile_input((SWITCH [0,1]));
__ASTREE_max_clock((3600000));
$\{P=(P-((((2.0 * P)-A)-B) * 5.0 e-03)$ astnee -exec-fn main -config-sem retro.config
$B=A ; \quad$ retro.c | grep "|P|" | tail -n 1
$|P|<=1.0000002 *((15 .+$
$\begin{array}{ll}\text { else }\{\mathrm{A}=\mathrm{X} ;\} & 5.8774718 \mathrm{e}-39 /(1.0000002-1)) *(1.0000002)^{c} l \text { ock }\end{array} \quad-$
23.039353

## Non-numerical abstraction used in Astrée

- Code Sample:

```
/* boolean.c */
typedef enum {F=0,T=1} BOOL;
BOOL B;
void main () {
    unsigned int X, Y;
    while (1) {
        B = (X == 0);
        if (!B) {
        Y = 1 / X;
        }
        }
}
```

The boolean relation abstract domain is parameterized by the height of the decision tree (an analyzer option) and the abstract domain at the leafs

## Reduction of Abstractions

Example: reduction of intervals [CC76] by simple congruences [Gra89]

```
% cat -n congruence.c
    1 /* congruence.c */
    2 int main()
    3 { int X;
    4 X = 0;
    5 while (X <= 128)
    6 { X = X + 4; };
    7 __ASTREE_log_vars((X));
    8 }
% astree congruence.c -no-relational -exec-fn main |& egrep "(WARN)|(X in)"
direct = <integers (intv+cong+bitfield+set): X in {132} >
Intervals : X [ [129,132] + congruences : X = 0 mod 4\Longrightarrow
X \in{132}.
```

## Examples of Static Analyzers in Industrial Use

- For C critical synchronous embedded control/command pro grams (for example for Electric Flight Control Software)
- aiT $\left[\mathrm{FHL}^{+} 01\right]$ is a static analyzer to determine the Worst Case Execution Time (to guarantee synchronization in due time)
- Astrée $\left[\mathrm{BCC}^{+} 03\right]$ is a static analyzer to verify the absence of runtime errors

## Examples of Programs Analyzed by Astrée

- Automatic proofs of absence of runtime errors in Electric Flight Control Software:
- A340/600: 132.000 lines of C, 40 mn on a PC $2.8 \mathrm{GHz}, 300 \mathrm{Mb}$ (Nov. 2003)
- A380: 1.000.000 lines of C, 34h, 8 Gb (Nov. 2005) no false alarm, World premières !
- Automatic proofs of absence of runtime errors in the ATV software ${ }^{(2)}$ :
- C version of the automatic docking software: 102.000 lines of C, 23s on a Quad-Core AMD Opteron ${ }^{\text {TM }}$ processor, 16 Gb (Apr. 2008)
(2) the Jules Vernes Automated Transfer Vehicle (ATV) enabling ESA to transport payloads to the International Space Station.

In this gentle introduction to Abstract Interpretation

Collecting semantics: partial traces

Octagons:
$\pm \mathrm{x} \pm \mathrm{y} \leqslant a$

Intervals.

$$
\mathrm{x} \in[a, b]
$$

Ellipses.
$\mathrm{x}^{2}+b \mathrm{y}^{2}-a \mathrm{xy} \leqslant d$

Simple congruences:

$$
\mathrm{x} \equiv a[b]
$$

Exponentials:
$-a^{b t} \leqslant \mathrm{y}(t) \leqslant a^{b t}$

## Mathematical Semantics

## A sample program

Let us start with the following example program.

$$
P \triangleq{ }^{1} \mathrm{x}:=1 ; \text { while }{ }^{2} \text { true do }{ }^{3} \mathrm{x}:=(\mathrm{x}+1) ; \text { od }^{4} .
$$

## A sample program

Let us start with the following example program.

$$
P \triangleq{ }^{1} \mathrm{x}:=1 ; \text { while }{ }^{2} \text { true do }{ }^{3} \mathrm{x}:=(\mathrm{x}+1) ; \text { od }^{4} .
$$

The mathematical semantics of this program can be informally described at follows.

- Execution start at program point ${ }^{1}$ by assigning 1 to program variable $x$ and goes on at program point ${ }^{2}$.
- When at program point ${ }^{2}$ the evaluation of the loop test yields the value $\mathfrak{t r u e}$ so execution continues at program ${ }^{3}$ where the value of variable x is incremented by 1 before coming back to ${ }^{2}$.
- Since the loop condition is never false, program point ${ }^{4}$ is unreachable so program execution never ends.

## States

$P \triangleq{ }^{1} \mathrm{x}:=1$; while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1)$; od ${ }^{4}$.

More formally, we write $\left\langle{ }^{\ell}, x\right\rangle$ for the state of program execution where execution is at program point $\ell, \ell={ }^{1}, 2^{3},{ }^{4}$, and variable x has integer value $x \in \mathbb{Z}$ (where $\mathbb{Z}$ is the set of all mathematical integers).

## Execution trace

$\boldsymbol{P} \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1) ;$ od $^{4}$.

A complete program execution can be described by the following execution trace which is an infinite sequence of states

$$
\left\langle{ }^{1}, z\right\rangle\left\langle^{2}, 1\right\rangle\left\langle^{3}, 1\right\rangle\left\langle^{2}, 2\right\rangle\left\langle^{3}, 2\right\rangle \ldots\left\langle^{2}, i\right\rangle\left\langle^{3}, i\right\rangle\left\langle^{2}, i+1\right\rangle \ldots
$$

where $z \in \mathbb{Z}$ can be any initial integer value of x .

## Trace semantics

$$
P \triangleq{ }^{1} \mathrm{x}:=1 ; \text { while }{ }^{2} \text { true do }{ }^{3} \mathrm{x}:=(\mathrm{x}+1) ; \text { od }^{4} .
$$

So the set of all such execution traces is

$$
\left\{\left\langle{ }^{1}, z\right\rangle\left\langle^{2}, 1\right\rangle\left\langle^{3}, 1\right\rangle\left\langle^{2}, 2\right\rangle\left\langle^{3}, 2\right\rangle \ldots\left\langle^{2}, i\right\rangle\left\langle^{3}, i\right\rangle\left\langle^{2}, i+1\right\rangle \ldots \mid z \in \mathbb{Z}\right\}
$$

## Mathematical Invariants

## Invariance abstraction

$P \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1)$; od ${ }^{4}$.

Let us now consider an abstraction of the set of all possible execution traces, which consists in remembering for each program point $\ell, \ell={ }^{1}, 2,{ }^{3}, 4$ the set $I_{\ell}$ of possible values that can be taken by variable x when execution reaches program point $\ell$ along any of these traces.

## Invariance semantics

$\boldsymbol{P} \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1) ;$ od $^{4}$.

This set $I_{\ell}$ is called a program local invariant at program point $\ell$. We have

$$
\begin{aligned}
& I_{1}=\mathbb{Z} \\
& I_{2}=\{z \in \mathbb{Z} \mid z>0\} \\
& I_{3}=\{z \in \mathbb{Z} \mid z>0\} \\
& I_{4}=\emptyset
\end{aligned}
$$

## Traces to invariants abstraction

$$
\alpha(T)=\lambda l .\left\{x \mid \exists \sigma, \sigma^{\prime}: \sigma\langle l, x\rangle \sigma^{\prime} \in T\right\}
$$

The abstraction $\alpha$ maps a set $T$ of traces to a map $\alpha(T)$ from program points $l$ to the set $\alpha(T) l$ of reachable values $X$ of program variable $x$ during any possible execution in $T$.

## Mathematical Invariant Equations

## Invariance Equations

$P \triangleq{ }^{1} \mathrm{x}:=1$; while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1)$; od ${ }^{4}$.

Observe that the set $I_{\ell}$ of possible values of variable x at program point $\ell=$ ${ }^{1,2,3,4}$ satisfies the following conditions.

$$
\left\{\begin{array}{l}
X_{1}=\mathbb{Z} \\
X_{2}=\{1\} \cup\left\{x+1 \mid x \in X_{3}\right\}  \tag{3.1}\\
X_{3}=X_{2} \cap\{x \in \mathbb{Z} \mid \text { true }\} \\
X_{4}=X_{2} \cap\{x \in \mathbb{Z} \mid \text { false }\}
\end{array}\right.
$$

## Invariance Equations

- At program point ${ }^{1}$ the variable x can be initialized by any integer value $z \in \mathbb{Z}$ and so $X_{1}=\mathbb{Z}$
- At program point ${ }^{2}$, either execution comes from program point ${ }^{1}$ and so the value of variable x is 1 or execution comes from program point ${ }^{2}$ and so the value of variable x is the value $x$ that x had at this point ${ }^{3}$ incremented by 1. So $X_{2}=\{1\} \cup\left(\left\{x+1 \mid x \in X_{3}\right\}\right.$.
- At program point ${ }^{3}$, the possible values of x are those at point ${ }^{2}$ for which the loop condition is true so $X_{3}=X_{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}=X_{2}$.
- At program point ${ }^{4}$, the possible values of $x$ are those at point ${ }^{2}$ for which the loop condition is false so $X_{4}=X_{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}=\emptyset$.

## Fixpoint Equations

These conditions can be understood as a system of fixpoint equations $X=f(X)$ of the form

$$
\left\{\begin{array}{l}
X_{i}=f_{i}\left(X_{1}, \ldots, X_{4}\right) \\
i=1, \ldots, 4
\end{array}\right.
$$

with unknowns $X=\left\langle X_{1}, \ldots, X_{4}\right\rangle$.

## Fixpoint Solutions

$$
\left\{\begin{array}{l}
X_{1}=\mathbb{Z} \\
X_{2}=\{1\} \cup\left\{x+1 \mid x \in X_{3}\right\}  \tag{3.1}\\
X_{3}=X_{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\} \\
X_{4}=X_{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}
\end{array}\right.
$$

- So solving this system of equations might lead to the desired invariant $I$.
- However these equations do not have a unique solution. For example $X_{1}=X_{2}=X_{3}=\mathbb{Z}$ and $X_{4}=\emptyset$ is another solution which is larger for componentwise set inclusion $\subseteq$.
- So we will prefer the smallest solution (called the least fixpoint lfp $f$ ), which is included in all other solutions ${ }^{1}$ and turns out to be $I$.

[^0]
## Tarski's fixpoint theorem

## Fixpoints of increasing functions (Tarski)

## Fixpoint

- Let $S$ be a set
- Let $F$ be a function $F \in S \longrightarrow S$
- A fixpoint of $F$ is $x \in S$ such that

$$
x=F(x)
$$

- i.e. a solution to the equation

## Least fixpoint

- Let $\langle\mathrm{S}, \leqslant\rangle$ be a set partially ordered by $\leqslant$
- The least fixpoint, if any, of $F \in S \longrightarrow S$ is
- a fixpoint $x=F(x)$
- $\leqslant$-smaller than any other fixpoint

$$
y=F(y) \quad \Longrightarrow x \leqslant y
$$

- Notation: Lfp F

## Tarski's fixpoint theorem

- let $S$ be a set
- $\mathscr{P}(S)=\{X \mid X \subseteq S\}$ is the power
(so $\langle\mathscr{P}(S), \subseteq\rangle$ is a set partially ordered by $\subseteq$ )
- $F \in \mathscr{P}(S) \longrightarrow \mathscr{P}(S)$ is increasing i.e.

$$
X \subseteq Y \Longrightarrow F(X) \subseteq F(Y)
$$

implies

- Ifp $F=\cap\{X \mid F(X) \subseteq X\}$

## Example

fincreasing

f not increasing

# Solving the Equations by Exhaustive Enumeration 

## Example

iteration from infimum

## Solving the equations iteratively ...

The least solution $I=\operatorname{lfp} f$ of $X=f(X)$ for $\subseteq$ can be calculated iteratively, essentially by enumeration of all possible states reachable from the initial states.

## Solving the equations iteratively ... (Cont'd)

- $X^{0}=\left\langle X_{1}^{0}, X_{2}^{0}, X_{3}^{0}, X_{4}^{0}\right\rangle=\langle\emptyset, \emptyset, \emptyset, \emptyset\rangle \quad$ 2starting with the smallest possible approximations

## Solving the equations iteratively ... (Cont'd)

- $X^{0}=\left\langle X_{1}^{0}, X_{2}^{0}, X_{3}^{0}, X_{4}^{0}\right\rangle=\langle\emptyset, \emptyset, \emptyset, \emptyset\rangle \quad$ 2starting with the smallest possible approximations

$$
\begin{aligned}
- & X^{1}=\left\langle X_{1}^{1}, X_{2}^{1}, X_{3}^{1}, X_{4}^{1}\right\rangle=f\left(X^{0}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{0}\right\}\right. \\
& \left.X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\}, \emptyset, \emptyset\rangle
\end{aligned}
$$

## Solving the equations iteratively ... (Cont'd)

- $X^{0}=\left\langle X_{1}^{0}, X_{2}^{0}, X_{3}^{0}, X_{4}^{0}\right\rangle=\langle\emptyset, \emptyset, \emptyset, \emptyset\rangle \quad$ 2starting with the smallest possible approximations

$$
\begin{aligned}
- & X^{1}=\left\langle X_{1}^{1}, X_{2}^{1}, X_{3}^{1}, X_{4}^{1}\right\rangle=f\left(X^{0}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{0}\right\},\right. \\
& \left.X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\}, \emptyset, \emptyset\rangle
\end{aligned}
$$

$$
-X^{2}=\left\langle X_{1}^{2}, X_{2}^{2}, X_{3}^{2}, X_{4}^{2}\right\rangle=f\left(X^{1}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{1}\right\},\right.
$$

$$
\left.X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\},\{1\}, \emptyset\rangle
$$

## Solving the equations iteratively ... (Cont'd)

- $X^{0}=\left\langle X_{1}^{0}, X_{2}^{0}, X_{3}^{0}, X_{4}^{0}\right\rangle=\langle\emptyset, \emptyset, \emptyset, \emptyset\rangle \quad$ starting with the smallest possible approximations

$$
\begin{aligned}
- & X^{1}=\left\langle X_{1}^{1}, X_{2}^{1}, X_{3}^{1}, X_{4}^{1}\right\rangle=f\left(X^{0}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{0}\right\},\right. \\
& \left.X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\}, \emptyset, \emptyset\rangle
\end{aligned}
$$

$$
-X^{2}=\left\langle X_{1}^{2}, X_{2}^{2}, X_{3}^{2}, X_{4}^{2}\right\rangle=f\left(X^{1}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{1}\right\}\right.
$$

$$
\left.X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\},\{1\}, \emptyset\rangle
$$

$$
-X^{3}=\left\langle X_{1}^{3}, X_{2}^{3}, X_{3}^{3}, X_{4}^{3}\right\rangle=f\left(X^{2}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{2}\right\}\right.
$$

$$
\left.X_{2}^{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1,2\},\{1\}, \emptyset\rangle
$$

## Solving the equations iteratively ... (Cont'd)

- $X^{0}=\left\langle X_{1}^{0}, X_{2}^{0}, X_{3}^{0}, X_{4}^{0}\right\rangle=\langle\emptyset, \emptyset, \emptyset, \emptyset\rangle \quad$ 2starting with the smallest possible approximations
$-X^{1}=\left\langle X_{1}^{1}, X_{2}^{1}, X_{3}^{1}, X_{4}^{1}\right\rangle=f\left(X^{0}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{0}\right\}\right.$, $\left.X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{0} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\}, \emptyset, \emptyset\rangle$
$-X^{2}=\left\langle X_{1}^{2}, X_{2}^{2}, X_{3}^{2}, X_{4}^{2}\right\rangle=f\left(X^{1}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{1}\right\}\right.$, $\left.X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{1} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1\},\{1\}, \emptyset\rangle$
$-X^{3}=\left\langle X_{1}^{3}, X_{2}^{3}, X_{3}^{3}, X_{4}^{3}\right\rangle=f\left(X^{2}\right)=\left\langle\mathbb{Z},\{1\} \cup\left\{x+1 \mid x \in X_{3}^{2}\right\}\right.$, $\left.X_{2}^{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z},\{1,2\},\{1\}, \emptyset\rangle$
This calculation can go on like this ad infinitum since each iteration $X^{i+1}=$ $f\left(X^{i}\right)$ of the equations corresponds to an iteration in the program loop and so adds one more possible value of variable x at program point ${ }^{2}$. The solution is to use mathematical induction which requires to invent the following inductive hypothesis

## Solving the equations iteratively ... (Cont'd)

$-X^{2 n}=\left\langle X_{1}^{2 n}, X_{2}^{2 n}, X_{3}^{2 n}, X_{4}^{2 n}\right\rangle=\langle\mathbb{Z},\{1, \ldots, n\},\{1, \ldots, n\}, \emptyset\rangle$ 2induction hypothesis which holds for the basis $n=1\}$

## Solving the equations iteratively ... (Cont'd)

$-X^{2 n}=\left\langle X_{1}^{2 n}, X_{2}^{2 n}, X_{3}^{2 n}, X_{4}^{2 n}\right\rangle=\langle\mathbb{Z},\{1, \ldots, n\}, \quad\{1, \ldots, n\}, \quad \emptyset\rangle$ induction hypothesis which holds for the basis $n=1 \mathrm{~S}$
$-X^{2 n+1}=\left\langle X_{1}^{2 n+1}, X_{2}^{2 n+1}, X_{3}^{2 n+1}, X_{4}^{2 n+1}\right\rangle=f\left(X^{2 n}\right)=\langle\mathbb{Z},\{1\} \cup\{x+$ $\left.\left.1 \mid x \in X_{3}^{2 n}\right\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z}$, $\{1, \ldots, n+1\},\{1, \ldots, n\}, \emptyset\rangle$

## Solving the equations iteratively ... (Cont'd)

$-X^{2 n}=\left\langle X_{1}^{2 n}, X_{2}^{2 n}, X_{3}^{2 n}, X_{4}^{2 n}\right\rangle=\langle\mathbb{Z},\{1, \ldots, n\}, \quad\{1, \ldots, n\}, \emptyset\rangle$ \{induction hypothesis which holds for the basis $n=1\}$
$-X^{2 n+1}=\left\langle X_{1}^{2 n+1}, X_{2}^{2 n+1}, X_{3}^{2 n+1}, X_{4}^{2 n+1}\right\rangle=f\left(X^{2 n}\right)=\langle\mathbb{Z},\{1\} \cup\{x+$ $\left.\left.1 \mid x \in X_{3}^{2 n}\right\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z}$, $\{1, \ldots, n+1\},\{1, \ldots, n\}, \emptyset\rangle$

- $X^{2 n+2}=\left\langle X_{1}^{2 n+2}, X_{2}^{2 n+2}, X_{3}^{2 n+2}, X_{4}^{2 n+2}\right\rangle=f\left(X^{2 n+1}\right)=\langle\mathbb{Z},\{1\} \cup$ $\left\{x+1 \mid x \in X_{3}^{2 n+1}\right\}, X_{2}^{2 n+1} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2 n+1} \cap\{x \in \mathbb{Z} \mid$ $\mathfrak{f a l s e}\}\rangle=\langle\mathbb{Z},\{1, \ldots, n+1\},\{1, \ldots, n+1\}, \emptyset\rangle$

## Solving the equations iteratively ... (Cont'd)

$-X^{2 n}=\left\langle X_{1}^{2 n}, X_{2}^{2 n}, X_{3}^{2 n}, X_{4}^{2 n}\right\rangle=\langle\mathbb{Z},\{1, \ldots, n\}, \quad\{1, \ldots, n\}, \emptyset\rangle$ induction hypothesis which holds for the basis $n=1 \mathrm{~S}$
$-X^{2 n+1}=\left\langle X_{1}^{2 n+1}, X_{2}^{2 n+1}, X_{3}^{2 n+1}, X_{4}^{2 n+1}\right\rangle=f\left(X^{2 n}\right)=\langle\mathbb{Z},\{1\} \cup\{x+$ $\left.\left.1 \mid x \in X_{3}^{2 n}\right\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2 n} \cap\{x \in \mathbb{Z} \mid \mathfrak{f a l s e}\}\right\rangle=\langle\mathbb{Z}$, $\{1, \ldots, n+1\},\{1, \ldots, n\}, \emptyset\rangle$
$-X^{2 n+2}=\left\langle X_{1}^{2 n+2}, X_{2}^{2 n+2}, X_{3}^{2 n+2}, X_{4}^{2 n+2}\right\rangle=f\left(X^{2 n+1}\right)=\langle\mathbb{Z},\{1\} \cup$ $\left\{x+1 \mid x \in X_{3}^{2 n+1}\right\}, X_{2}^{2 n+1} \cap\{x \in \mathbb{Z} \mid \mathfrak{t r u e}\}, X_{2}^{2 n+1} \cap\{x \in \mathbb{Z} \mid$ $\mathfrak{f a l s e}\}\rangle=\langle\mathbb{Z},\{1, \ldots, n+1\},\{1, \ldots, n+1\}, \emptyset\rangle$

- By recurrence on $n$, we have proved that
$\forall n: X^{2 n}=\left\langle X_{1}^{2 n}, X_{2}^{2 n}, X_{3}^{2 n}, X_{4}^{2 n}\right\rangle=\langle\mathbb{Z},\{1, \ldots, n\},\{1, \ldots, n\}, \emptyset\rangle$

## Solving the equations iteratively ... (Cont'd)

- Passing to the limit, we get the desired strongest invariant

$$
\begin{aligned}
& I=\left\langle I_{1}, I_{2}, I_{3}, I_{4}\right\rangle \\
= & \lim _{n \rightarrow+\infty} X^{2 n} \\
= & \langle\mathbb{Z},\{n \in \mathbb{Z} \mid n>0\},\{n \in \mathbb{Z} \mid n>0\}, \emptyset\rangle
\end{aligned}
$$

## $f$ is increasing

- A fundamental property of the invariants equations $X=f(X)$ is that $f$ is increasing.
- This means that if $X \subseteq Y$ then $f(X) \subseteq f(Y)$ where $\left\langle X_{1}, \ldots, X_{n}\right\rangle \subseteq\left\langle Y_{1}\right.$, $\left.\ldots, Y_{n}\right\rangle$ if and only if $\forall i \in[1, n]: X_{i} \subseteq Y_{i}$.
- The intuition is that if more states can be reached at some program point then more states will be reachable at next program point.
- It follows that the iterates form an ascending chain meaning $X^{0} \subseteq X^{1} \subseteq$ $\ldots \dot{\subseteq} X^{n} \subseteq X^{n+1} \subseteq \ldots \dot{\subseteq} \lim _{n \rightarrow+\infty} X^{n}=\operatorname{lfp} f$.

## Machine Invariants

## Machine Integers

- No computer can represent any, arbitrary large, integer. In practice integer variables like x take their values in an interval [min_int, max_int] where min_int $<0<$ max_int are machine dependant ${ }^{2}$.
- It follows that we have to decide what happens in case of overflow when evaluating expression $(x+1)$.
- We will assume that execution immediately stops in case of integer overflow ${ }^{3}$.

[^1]
## Machine states and execution traces

Hence the set of program states $\mathcal{S} \triangleq\{1,2,3,4\} \times[$ min_int, max_int $]$ is now finite and the execution traces are now finite of the form

$$
\begin{aligned}
& \left\{\left\langle^{1}, z\right\rangle\left\langle^{2}, 1\right\rangle \ldots\left\langle^{2}, i\right\rangle\left\langle^{3}, i\right\rangle\left\langle^{2}, i+1\right\rangle \ldots\left\langle^{3}, \text { max_int }\right\rangle \mid z \in[\text { min_int },\right. \\
& \text { max_int }]\} .
\end{aligned}
$$

## Machine Invariant Equations

$P \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1) ;$ od $^{4}$.

It follows that the machine invariant satisfies the following equations

$$
\left\{\begin{array}{l}
X_{1}=[\text { min_int }, \text { max_int }] \\
X_{2}=\{1\} \cup\left\{x+1 \in[\text { min_int, max_int }] \mid x \in X_{3}\right\}  \tag{3.2}\\
X_{3}=X_{2} \cap\{x \in[\text { min_int, max_int }] \mid \mathfrak{t r u e}\} \\
X_{4}=X_{2} \cap\{x \in[\text { min_int, max_int }] \mid \text { false }\}
\end{array}\right.
$$

## Converoence

- Now the convergence of the iterations is guaranteed but is so slow that it cannot be of any practical use, but for programs with very few program variables.
- Moreover, mathematical sets of integers can be arbitrarily complex hence very expensive to represent in computer memory which is likely to produce memory overflows after lengthy computations, a flaw of all program verification methods based upon the exhaustive enumeration of all possible cases.

## Interval Abstraction

## Interval Abstraction

- A further abstraction must be used to solve the machine invariant computer representation problem.

## Interval Abstraction

- A further abstraction must be used to solve the machine invariant computer representation problem.
- We will use intervals $[l, h] \triangleq\{x \in \mathbb{Z} \mid l \leqslant x \leqslant h\}$ with the convention that $[l, h]=\emptyset$ whenever $h<l$.

Intervals:

$$
\mathbf{x} \in[a, b]
$$

## Interval Abstraction

- A further abstraction must be used to solve the machine invariant computer representation problem.
- We will use intervals $[l, h] \triangleq\{x \in \mathbb{Z} \mid l \leqslant x \leqslant h\}$ with the convention that $[l, h]=\emptyset$ whenever $h<l$.
- In doing so we perform an approximation of a non-empty set $X \subseteq[$ min_int, max_int] by the interval $[\min X, \max X$.

## Interval Abstraction

- A further abstraction must be used to solve the machine invariant computer representation problem.
- We will use intervals $[l, h] \triangleq\{x \in \mathbb{Z} \mid l \leqslant x \leqslant h\}$ with the convention that $[l, h]=\emptyset$ whenever $h<l$.
- In doing so we perform an approximation of a non-empty set $X \subseteq[$ min_int, max_int] by the interval $[\min X, \max X$ ].
- This approximation is sound in that whenever the value of variable x belongs to a set $X_{i}$ whenever execution reaches program point ${ }^{i}$, it definitely also belongs to the set $\left[\min X_{i}, \max X_{i}\right.$ ].

## Interval Abstraction

- A further abstraction must be used to solve the machine invariant computer representation problem.
- We will use intervals $[l, h] \triangleq\{x \in \mathbb{Z} \mid l \leqslant x \leqslant h\}$ with the convention that $[l, h]=\emptyset$ whenever $h<l$.
- In doing so we perform an approximation of a non-empty set $X \subseteq[$ min_int, max_int] by the interval $[\min X, \max X$ ].
- This approximation is sound in that whenever the value of variable x belongs to a set $X_{i}$ whenever execution reaches program point ${ }^{i}$, it definitely also belongs to the set $\left[\min X_{i}, \max X_{i}\right.$ ].
- This information is certainly correct but just less precise.
- The interval invariance equations are now

## Traces to intervals abstraction

$$
\alpha(T)=\lambda l . \text { let } X=\left\{x \mid \exists \sigma, \sigma^{\prime}: \sigma\langle l, x\rangle \sigma^{\prime} \in T\right\} \text { in }
$$

## $[\min X, \max X]$

The abstraction $\alpha$ maps a set $T$ of traces to a map $\alpha(T)$ from program points $l$ to the pair $(\mathrm{m}, \mathrm{M})=\alpha(T) l$ of minimal m and maximal M reachable values $x$ of program variable x during any possible execution in $T$.

## Interval Invariance Equations

$P \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1) ;$ od $^{4}$.

The interval invariance equations are now

$$
\left\{\begin{aligned}
X_{1}= & {[\text { min_int, max_int }] } \\
X_{2}= & {[1,1] \sqcup \emptyset X_{3}=\emptyset \text { ? } \emptyset: \text { let }[a, b]=X_{3} \text { in } } \\
& {[\min (a+1, \text { max_int }), \min (b+1, \text { max_int })]) } \\
X_{3}= & X_{2} \sqcap[\text { min_int, max_int }] \\
X_{4}= & X_{2} \sqcap \emptyset
\end{aligned}\right.
$$

Note: these equations are correct but imprecise since if $X 3=$ [max_int,max_int], we get X2 $=[1, \mathrm{I}] ~ \sqcup$ [max_int,max_int], while $\mathrm{X} 2=[1, \mathrm{I}] \sqcup \varnothing$ would be correct and more precise.

## Interval Operations

- where the interval join is $\emptyset \sqcup \emptyset \triangleq \emptyset, \emptyset \sqcup[l, h] \triangleq[l, h] \sqcup \emptyset \triangleq[l, h]$, and

$$
[a, b] \sqcup[c, d] \triangleq[\min (a, c), \max (b, d)]
$$

- and the interval meet is $\emptyset \sqcap \emptyset \triangleq \emptyset, \emptyset \sqcap[l, h] \triangleq[l, h] \sqcap \emptyset \triangleq \emptyset$, and

$$
\begin{array}{ll}
{[a, b] \sqcap[c, d] \triangleq[\max (a, c), \min (b, d)]} & \text { when } b \geqslant c \wedge d \geqslant a \\
{[a, b] \sqcap[c, d] \triangleq \emptyset} & \text { when } b<c \vee d<a
\end{array}
$$

## Over-approximation

- The interval equations over-estimate the machine invariant in than they will provide in general more states that possible in actual program executions. - For example the set $\{1,2,5\}$ will be overapproximated by $[1,5]$ which introduces the spurious values 3 and 4 .
- Notice that overapproximation preserve invariance. For example if the values of variable x are always greater than one at some program point then they are certainly positive (although the value 0 is spurious).

## Example of incorrect approximations

## For $x \in\{1,2,5\}$

- Underapproximations (such as x is always equal to 1 ) would be incorrect.
- Similarly, incomparable approximations (such as x is negative) are also unsound. In particular the interval join $\sqcup$ overapproximates the interval union $\cup$ and the interval meet $\Pi$ overapproximates the interval intersection $\cap$.

## An Interval Abstract Interpreter

## Objective

- We now briefly sketch the design and functional encoding in OCAML of the interval abstract interpreter.
- Such an interval abstract interpreter reads any program, builds the interval invariance equations, and then solve them.
- For simplicity, we concentrate on the second part and will provide encodings of the interval invariance equations manually.

Ocaml is a functional programming language with a compiler and associated tools freely available for all laptop operating systems at http://ocaml.org

## The Interval Abstract Domain

- We first encode the interval abstract domain, implementing a computer representation of abstract interval propeties with a type interval (where EMPTY encodes the empty set Ø). In OCaml, we have max_int $=1073741823$ and min_int $=-1073741824{ }^{4}$.
- We also encode the basic interval operations $\sqsubseteq$ (less, interval inclusion), $\sqcup$ (interval join), $\sqcap$ (interval meet), interval printing (print) and interval incrementation (add1).
- Of course many more interval operations are needed to handle a full language, but we aim at extreme simplicity.
${ }^{4}$ One of the 64 bits is used for garbage collection. or max_int $=4611686018427387903$ depending on the machine/compiler

```
(* interval.ml, interval abstract domain *)
type interval = EMPTY | INT of (int * int);;
let less x y = match x,y with
    | EMPTY, _ -> true
| _, EMPTY -> false
| INT (a,b), INT (c,d) -> (c<=a)&&(b<=d);;
let greater x y = less y x;;
let join x y = match x,y with
    | EMPTY, _ -> y
    | _, EMPTY -> x
| INT (a,b), INT (c,d) -> INT (min a c,max b d);;
let meet x y = match x,y with
    | EMPTY, _ -> EMPTY
    | _, EMPTY -> EMPTY
| INT (a,b), INT (c,d) ->
        if (b<c) || (d<a) then EMPTY
        else INT (max a c,min b d);;
let add1 x = match x with
    | EMPTY -> EMPTY
    | INT (a,b) ->
        (INT ((if a<max_int then a+1 else max_int),
        (if b<max_int then b+1 else max_int)));;
let print x = match x with
    | EMPTY -> print_string "_l_ "
    | INT (a,b) -> print_string "("; print_int a;
        print_string ","; print_int b; print_string ") ";;
```

## Abstract Environments

- For programs with more than one variable, we would have to encode an abstract environment assigning intervals to program variables.
- Writing $X=\left\{\mathrm{x}_{1} \leftarrow v_{1}, \ldots, \mathrm{x}_{n} \leftarrow v_{n}\right\}$ for the function $X$ mapping $\mathrm{x}_{i}$ to $v_{i}$ such that $X\left(\mathrm{x}_{i}\right)=v_{i}, i=1, \ldots, n$, the interval invariance equations would be

$$
\begin{aligned}
& {\left[X_{1}=\{\mathrm{x} \leftarrow \text { [min_int, max_int }]\right\}} \\
& X_{2}=\left\{\mathrm { x } \leftarrow [ 1 , 1 ] \sqcup \left(X_{3}(\mathrm{x})=\emptyset \text { ə } \emptyset: \operatorname{let}[a, b]=X_{3}(\mathrm{x})\right.\right. \text { in } \\
& [\min (a+1, \text { max_int }), \min (b+1, \text { max_int })] D\} \\
& \left.X_{3}=X_{2} \dot{\Pi}\{x \leftarrow \text { [min_int, max_int }]\right\} \\
& X_{4}=X_{2} \dot{\Pi}\{x \leftarrow \emptyset\}
\end{aligned}
$$

where the abstract operations are extended pointwise such as $\left\{\mathrm{x}_{1} \leftarrow v_{1}, \ldots\right.$, $\left.\mathrm{x}_{n} \leftarrow v_{n}\right\} \dot{\Pi}\left\{\mathrm{x}_{1} \leftarrow v_{1}^{\prime}, \ldots, \mathrm{x}_{n} \leftarrow v_{n}^{\prime}\right\} \triangleq\left\{\mathrm{x}_{1} \leftarrow v_{1} \sqcap v_{1}^{\prime}, \ldots, \mathrm{x}_{n} \leftarrow v_{n} \sqcap v_{n}^{\prime}\right\}$.

- Since our example has only one variable, this boils down to using the interval abstract domain (and leaving implicit the variable name x ).

## Abstract Invariants

- Then we have to encode an abstract domain for representing abstract invariants $\left\langle X^{1}, X^{2}, X^{3}, X^{4}\right\rangle$ which attach to each program point ${ }^{i}$ an abstract local invariant $X^{i}$ which holds whenever controls reaches program point ${ }^{i}$.
- Each abstract local invariant $X^{i}$ is represented by an abstract environment (abstract intervals in our simplified case).
- The encoding is very simple as a 4-tuple specifying the value of program variable x at each program point $\left({ }^{1},{ }^{2}, 3,4\right)$.

## Abstract Invariants (Cont'd)

We essentially have to represent the logical structure, which boils down to

- the partial order $\sqsubseteq$ (pless), encoding abstract implication ( $\subseteq$ in set theory and $\Rightarrow$ in logic);
- $\doteq$ (pgreater), the abstract inverse implication $(\supseteq$ in set theory and $\Leftarrow$ in logic);
- the pointwise infimum $(\emptyset)^{4}$ (pbot), the abstract encoding of $\mathfrak{f a l s e}$,
- the pointwise meet (for later use)inabection 3.9), and
- the printing of local abstract invariants attached to program points (pprint).
(* invariant.ml, interval invariant abstract domain *) open Interval
type invariant = interval*interval*interval*interval;
let cless ( $\mathrm{x} 1, \mathrm{x} 2, \mathrm{x} 3, \mathrm{x} 4$ ) ( $\mathrm{x}^{\prime} 1, \mathrm{x}{ }^{\prime} 2, \mathrm{x}^{\prime} 3, \mathrm{x} \mathrm{A}^{\prime} 4$ ) =
(less x1 x'1, less x2 x'2, less $x 3$ x'3, less $x 4$ x'4); ;
let pless $x$ x' =
let (b1, b2, b3, b4) = cless $x x^{\prime}$ in b1 \&\& b2 \&\& b3 \&\& b4; ;
let pgreater $x x^{\prime}=$ pless $x$, $x ;$
let pbot $=$ (EMPTY, EMPTY, EMPTY, EMPTY); ;
let pmeet $(x 1, x 2, x 3, x 4)\left(x^{\prime} 1, x^{\prime} 2, x^{\prime} 3, x^{\prime} 4\right)=$
(meet $x 1 x^{\prime} 1$, meet $x 2 x^{\prime} 2$, meet $x 3 x^{\prime} 3$, meet $x 4 x^{\prime} 4$ ); ;
let pprint (x1, x2, x3, x4) =
print_string " 1:"; print x1; print_string " 2:";
print x2; print_string " 3:"; print x3;
print_string " 4:"; print x4; print_newline (); ;

## The Iterator

- Next the iterator module implements the iterative computation of the least solution of the invariance equations ( $\mathrm{lfp}^{5}$ ).
- It is parameterized by the order (leq), the starting point (a) and the abstract transformer $(f)$ so as to compute $a, f(a), f^{2}(a), \ldots, f^{n}(a), \ldots$, until reaching the limit $f^{\ell}(a)$ such that $f\left(f^{\ell}(a)\right) \sqsubseteq f^{\ell}(a)$.
- Of course, convergence may not be guaranteed in which case lfp does not terminate (or terminates with a runtime error, e.g. out of memory).

```
(* iterator.ml, iteration of f from a to x >= f(x) *)
let lfp leq a f =
    let rec iterate x =
        let y = f x in
            if leq y x then x
            else iterate y
    in iterate a;;
```

## Jacobi versus chaotic iteration strategies

Of course the Jacobi iteration strategy

$$
\left\{\begin{array}{l}
X_{i}^{k+1}=f_{i}\left(X_{1}^{k}, \ldots, X_{4}^{k}\right) \quad k=1,2,3, \ldots \\
i=1, \ldots, 4
\end{array}\right.
$$

is simplistic, more elaborate ones would use e.g. a working list

## Abstract Invariant Equations $X=f(X)$

Then we encode the abstract reachable state transformer $f(X)=f\left(\left\langle X_{1}\right.\right.$, $\left.\ldots, X_{4}\right\rangle$ ) using the environment abstract domain (the intervals in our simplified case).

```
(* transformerUnbounded.ml, abstract transformer *)
open Interval
open Invariant
let f1 () = INT (min_int,max_int); ;
let f2 x1 x3 = join (INT (1,1)) (add1 x3);;
let f3 x2 = meet x2 (INT (min_int,max_int)); ;
let f4 x2 = meet x2 EMPTY;;
let f (x1,x2,x3,x4) = (f1 (), f2 x1 x3, f3 x2, f4 x2);;
```

encoding:

$$
\left\{\begin{aligned}
X_{1}= & {[\text { min_int, max_int }] } \\
X_{2}= & {[1,1] \sqcup\left(X_{3}=\emptyset \text { \& } \emptyset: \operatorname{let}[a, b]=X_{3}\right. \text { in }} \\
& {\left[\min (a+1, \max -i n t), \min \left(b+1, \max _{-} i n t\right)\right] D } \\
X_{3}= & X_{2} \sqcap[\text { min_int, max_int }] \\
X_{4}= & X_{2} \sqcap \emptyset
\end{aligned}\right.
$$

## The Abstract Interpreter

The abstract interpreter performs the iterative abstract reachability fixpoint computation and prints the least fixpoint result.

```
(* reachability interval analysis *)
open Invariant
open TransformerUnbounded
open Iterator
let analyzer () = pprint (lfp pless pbot f);;
analyzer ();;
```

## Infinitary Iteration

## Iterative Resolution of the Interval Equations

Because the abstract domains are finite, the static analysis will always terminate. In our case, after more that 40 mn of computation ${ }^{6}$, we get

```
% ocamlc interval.ml invariant.ml transformeUnbounded.ml iterator.ml \
? reachability_unbounded.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1073741823) 4:_ l_
2977.460u 9.632s 50:43.46 98.1% 0+0k 0+0io 0pf+0w
%
```

${ }^{6}$ On a MacBook Pro with Intel Core 2 Duo at 2.6 GHz .

## A look at the iterates...

The Jacobi iterates are as follows

```
% ocamlc interval.ml invariant.ml transformerUnbounded.ml
? iteratorPartialUnboundedTrace.ml reachability_unbounded_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,2) 3:(1,1) 4:_l_

## On the Convergence Criterion

- Notice that the abstract invariance equations $X=f(X)$ are increasing, if $X \sqsubseteq Y$ then $f(X) \sqsubseteq f(Y)$.

## On the Convergence Criterion

- Notice that the abstract invariance equations $X=f(X)$ are increasing, if $X \sqsubseteq Y$ then $f(X) \sqsubseteq f(Y)$.
- The intuition is that the interval of possible value of a variable is larger at a program point, it should be also larger at the next program point.

## On the Convergence Criterion

- Notice that the abstract invariance equations $X=f(X)$ are increasing, if $X \sqsubseteq Y$ then $f(X) \sqsubseteq f(Y)$.
- The intuition is that the interval of possible value of a variable is larger at a program point, it should be also larger at the next program point.
- It follows that the iterates $X^{0} \sqsubseteq \ldots \sqsubseteq X^{n} \sqsubseteq \ldots \sqsubseteq \lim _{n \rightarrow+\infty} X^{n}$ are increasing.

## On the Convergence Criterion

- Notice that the abstract invariance equations $X=f(X)$ are increasing, if $X \sqsubseteq Y$ then $f(X) \sqsubseteq f(Y)$.
- The intuition is that the interval of possible value of a variable is larger at a program point, it should be also larger at the next program point.
- It follows that the iterates $X^{0} \sqsubseteq \ldots \sqsubseteq X^{n} \sqsubseteq \ldots 亡 \lim _{n \rightarrow+\infty} X^{n}$ are increasing.
- Since the abstract interpreter stops iterating when reaching of postfixpoint $f\left(\lim _{n \rightarrow+\infty} X^{n}\right) \sqsubseteq \lim _{n \rightarrow+\infty} X^{n}$, the limit satisfies $f\left(\lim _{n \rightarrow+\infty} X^{n}\right)=\lim _{n \rightarrow+\infty} X^{n}$ by antisymmetry.

## On Slow Convergence!

Of course the convergence is extremely slow and in practice must be accelerated.

## Convergence Acceleration

## Objective

- When convergence requires infinitely many steps or is very slow, it may not be possible, due to undecidability or high complexity, to exactly calculate the least solution to the abstract system of equations.(*)
${ }^{(*)}$ Of course direct solutions do sometimes exist e.g. linear equations on regular languages

## Objective

- When convergence requires infinitely many steps or is very slow, it may not be possible, due to undecidability or high complexity, to exactly calculate the least solution to the abstract system of equations. ${ }^{(*)}$
- The only sound solution is then to have overapproximations of the desired result.
(*) Of course direct solutions do sometimes exist e.g. linear equations on regular languages $_{\text {* }}$

- We now exploit the approximation idea a second time now while computing the solution of the invariance equations.
- The possibility of computing sound but approximate solutions to the invariant equations leads to powerful sound and fast static program analysis methods.
$\left(^{*}\right)$ Of course direct solutions do sometimes exist e.g. linear equations on regular languages

## Convergence Acceleration by Widening

## Convergence Acceleration by Widening

- The intuition for convergence acceleration is to speed up the increasing iteration $X^{0}=\perp, \ldots, X^{n+1}=f\left(X^{n}\right), \ldots, \lim _{n \rightarrow+\infty} X^{n}$ so as to reach an overapproximation $\hat{A}$ of the least solution $\lim _{n \rightarrow+\infty} X^{n}$ of the fixpoint equation $X=f(X)^{7}$.

[^2]since $f(\hat{A}) \sqsubseteq \hat{A}$ implies $\operatorname{Ifp} f \sqsubseteq \hat{A}$.

## Convergence Acceleration by Widening

- The intuition for convergence acceleration is to speed up the increasing iteration $X^{0}=\perp, \ldots, X^{n+1}=f\left(X^{n}\right), \ldots, \lim _{n \rightarrow+\infty} X^{n}$ so as to reach an overapproximation $\hat{A}$ of the least solution $\lim _{n \rightarrow+\infty} X^{n}$ of the fixpoint equation $X=f(X)^{7}$.
- Convergence acceleration means that $X^{n+1}$ will be a function of $X^{n}$ and $f\left(X^{n}\right)^{8}$ and so $X^{n+1}=X^{n} \nabla f\left(X^{n}\right)$ where $\nabla$ is called a widening ${ }^{9}$.

[^3]
## Soundness

- For soundness, the widening must perform over-approximations, that is $x \sqsubseteq$ $x \nabla y$ and $y \sqsubseteq x \nabla y$.

## Convergence enforcement

- For convergence, the widening must ensure termination with an overapproximation of the desired solution.

## Example: Interval Widening

For example, a widening for intervals could be

$$
\begin{aligned}
\emptyset \nabla y & \triangleq y \\
x \nabla \emptyset & \triangleq x \\
{[a, b] \nabla[c, d] } & \triangleq[0 c<a \text { 马 }-\infty: a \mid),(d>b \quad \text { 马 }+\infty: b)]
\end{aligned}
$$

## Example: Interval Widening

For example, a widening for intervals could be

$$
\begin{aligned}
\emptyset \nabla y & \triangleq y \\
x \nabla \emptyset & \triangleq x \\
{[a, b] \nabla[c, d] } & \triangleq[(c<a \text { ® }-\infty: a),(0 d>b \quad \text { 马 }+\infty: b)]
\end{aligned}
$$

- Recall than in $x \nabla y$ the $x$ is an iterate and $y$ is the next iterate $f(x)$. So in $[a, b] \nabla[c, d]$ if $c<a$ the next iterate decreases the lower limit of the interval so widening to $-\infty$ ensures this cannot happen infinitely often.

## Example: Interval Widening

For example, a widening for intervals could be

$$
\begin{aligned}
& \emptyset \nabla y \triangleq y \\
& x \nabla \emptyset \triangleq x \\
& {[a, b] \nabla[c, d] } \triangleq[(c<a \text { 马 }-\infty: a \emptyset, \cap d>b \\
&\text { ? }+\infty: b)
\end{aligned}
$$

- Recall than in $x \nabla y$ the $x$ is an iterate and $y$ is the next iterate $f(x)$. So in $[a, b] \nabla[c, d]$ if $c<a$ the next iterate decreases the lower limit of the interval so widening to $-\infty$ ensures this cannot happen infinitely often.
- Similarly, if $d>b$ then the next iterate increases the upper limit of the interval so widening to $+\infty$ ensures this cannot happen infinitely often. Moreover the widened interval is larger which ensures that we perform an overapproximation.

## Example: Interval Widening (Cont'd)

The extrapolation of bounds to infinity is illustrated on the following iteration (for two variables).

## Widenings are not increasing!

- Observe than the interval widening is not increasing. For example $[0,1] \sqsubseteq$ $[0,2]$ but $[0,1] \nabla[0,2]=[0,+\infty] \nsubseteq[0,2]=[0,2] \nabla[0,2]$, a point discussed at length in chapter 30.

## Widenings cannot be increasing!

- Observe than the interval widening is not increasing. For example $[0,1] \sqsubseteq$ $[0,2]$ but $[0,1] \nabla[0,2]=[0,+\infty] \nsubseteq[0,2]=[0,2] \nabla[0,2]$, a point discussed at length in chapter 30.
- It can be shown that if the widening stops loosing information when a solution is found and is increasing then it cannot enforce termination $\left(^{*}\right)$
${ }^{*}$ ) see P. Cousot, VMCAI 2015

## Encoding the interval widening

A functional encoding in of the widening in OCaml could be

```
(* intervalWidening.ml, interval widening *)
open Interval
let widen x y = match x,y with
| EMPTY, _ -> y
    _, EMPTY -> x
    INT (a,b), INT (c,d) ->
    let a' = if c<a then min_int else a in
        let b' = if d>b then max_int else b in
        INT (a',b,');;
```

## Environment Widening

If we had abstract environments to handle several variables, the widening would have to be applied individually for each of these variables.

## Invariant widening

$P \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1) ;$ od $^{4}$.

We must also extend the widening to local invariants attached to program points. In our example, the widening is applied once around the loop at program point ${ }^{2}$ as follows.

```
(* invariantWidening.ml, invariant widening *)
open IntervalWidening
let pwiden (x1,x2,x3,x4) (x'1,x'2,x'3,x'4) =
    (x'1,widen x2 x'2,x'3,x'4);;
```

## Abstract Interpreter with Widening

The abstract interpreter now calls the iterator using the invariant widening.

```
(* reachability analysis with widening *)
open Invariant
open InvariantWidening
open TransformerUnbounded
open Iterator
let analyzer () =
        let fw x = pwiden x (f x) in
        pprint (lfp pless pbot fw);;
analyzer (); ;
```

## Static Analysis with Widening

The result is now almost instantaneous.

```
% ocamlc interval.ml intervalWidening.ml invariant.ml \
? invariantWidening.ml transformerUnbounded.ml iterator.ml \
? reachability_widening.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1073741823) 4:_l_
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## Trace of the Iterations with Widening

The Jacobi iterates with widening are extremely fast as shown below.

```
% ocamlc interval.ml intervalWidening.ml invariant.ml \
? invariantWidening.ml transformerUnbounded.ml \
? iteratorTrace.ml reachability_widening_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_ |_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1, 1073741823) 4: _ _ _
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1073741823) 4:_ _ _
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## Imprecision of the Widening

Of course, the widening cannot, in general, provide the exact result! To see that, consider the bounded iteration

$$
P \triangleq{ }^{1} \mathrm{x}:=1 ; \operatorname{while}^{2}(\mathrm{x}<=100) \text { do }{ }^{3} \mathrm{x}:=(\mathrm{x}+1) ; \mathrm{od}^{4} .
$$

so that the abstract interval equations become

$$
\begin{aligned}
& \int X_{1}=\{\mathrm{x} \leftarrow[\text { min_int, max_int }]\} \\
& X_{2}=\left\{\mathrm { x } \leftarrow [ 1 , 1 ] \sqcup \left(X_{3}(\mathrm{x})=\emptyset \text { ? } \emptyset: \operatorname{let}[a, b]=X_{3}(\mathrm{x})\right.\right. \text { in } \\
& [\min (a+1, \text { max_int }), \min (b+1, \text { max_int })] D\} \\
& X_{3}=X_{2} \dot{\Pi}\{\mathrm{x} \leftarrow \text { [min_int, 100] }\} \\
& X_{4}=X_{2} \dot{\Pi}\left\{\mathrm{x} \leftarrow\left[101, \max _{\_} \text {int }\right]\right\}
\end{aligned}
$$

## I) Direct iteration (without widening)

A direct iteration

```
(* reachability interval analysis *)
open Invariant
open TransformerBounded
open Iterator
let analyzer () = pprint (lfp pless pbot f);;
analyzer (); ;
```

yields

```
% ocamlc interval.ml invariant.ml transformerBounded.ml \
? iterator.ml reachability_bounded.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
0.001u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## in more details

```
% ocamlc interval.ml invariant.ml transformerBounded.ml \
? iteratorPartialBoundedTrace.ml reachability_bounded_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,2) 3:(1,1) 4:_ |_
    1:(-1073741824,1073741823) 2:(1,2) 3:(1,2) 4:_l_
    1:(-1073741824,1073741823) 2:(1,3) 3:(1,2) 4:_l_
    1:(-1073741824,1073741823) 2:(1,99) 3:(1,99) 4:_ I_
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,99) 4:_ l_
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,100) 4:_l_
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:_l_
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
0.001u 0.001s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

Again convergence is guaranteed but slow.

## II) Iteration with widening

```
(* reachability analysis with widening *)
open Invariant
open InvariantWidening
open TransformerBounded
open Iterator
let analyzer () =
    let fw x = pwiden x (f x) in
    pprint (lfp pless pbot fw);;
analyzer ();;
```

we rapidly get a strictly less precise result.

```
% ocamlc interval.ml intervalWidening.ml invariant.ml \
? invariantWidening.ml transformerBounded.ml iterator.ml \
? reachability_widening_bounded.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,100) 4:(101,1073741823)
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
% ocamlc interval.ml intervalWidening.ml invariant.ml \
? invariantWidening.ml transformerBounded.ml iteratorTrace.ml \
```

In more details the widening effect is not compensated by the test on loop exit.

```
? reachability_widening_bounded_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_ l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1) 4:_ | _
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,100) 4:(101,1073741823)
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,100) 4:(101,1073741823)
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## Convergence Acceleration by Narrowing

## Intuition for Convergence Acceleration with Narrowing

- Because the upward iteration sequence with widening concerges to a postfixpoint $\hat{A}$ of $f$ such that $\operatorname{lfp} f \sqsubseteq \hat{A} \wedge f(\hat{A}) \sqsubseteq \hat{A}$, we have, by recurrence and since $f$ is increasing, that $\operatorname{lfp} f \sqsubseteq f^{n}(\hat{A}) \sqsubseteq \hat{A}$.

## Intuition for Convergence Acceleration with Narrowing

- Because the upward iteration sequence with widening concerges to a postfixpoint $\hat{A}$ of $f$ such that $\operatorname{lfp} f \sqsubseteq \hat{A} \wedge f(\hat{A}) \sqsubseteq \hat{A}$, we have, by recurrence and since $f$ is increasing, that $\operatorname{lfp} f \sqsubseteq f^{n}(\hat{A}) \sqsubseteq \hat{A}$.
- When $\hat{A}$ is not a fixpoint of $f$, any iterate in the sequence $Y^{0}=\hat{A}, \ldots$, $Y^{n+1}=f\left(Y^{n}\right)=f^{n}(\hat{A})$ is an overapproximation of the unknown lfp $f$ more precise than $\hat{A}$.

## Intuition for Convergence Acceleration with Narrowing

- Because the upward iteration sequence with widening concerges to a postfixpoint $\hat{A}$ of $f$ such that $\operatorname{lfp} f \sqsubseteq \hat{A} \wedge f(\hat{A}) \sqsubseteq \hat{A}$, we have, by recurrence and since $f$ is increasing, that $\operatorname{lfp} f \sqsubseteq f^{n}(\hat{A}) \sqsubseteq \hat{A}$.
- When $\hat{A}$ is not a fixpoint of $f$, any iterate in the sequence $Y^{0}=\hat{A}, \ldots$, $Y^{n+1}=f\left(Y^{n}\right)=f^{n}(\hat{A})$ is an overapproximation of the unknown Ifp $f$ more precise than $\hat{A}$.
- However, this downward iteration $\left\langle Y^{n}, n \in \mathbb{N}\right\rangle$ might be infinite or converging slowly.

## Intuition for Convergence Acceleration with Narrowing

- Because the upward iteration sequence with widening concerges to a postfixpoint $\hat{A}$ of $f$ such that $\operatorname{lfp} f \sqsubseteq \hat{A} \wedge f(\hat{A}) \sqsubseteq \hat{A}$, we have, by recurrence and since $f$ is increasing, that lfp $f \sqsubseteq f^{n}(\hat{A}) \sqsubseteq \hat{A}$.
- When $\hat{A}$ is not a fixpoint of $f$, any iterate in the sequence $Y^{0}=\hat{A}, \ldots$, $Y^{n+1}=f\left(Y^{n}\right)=f^{n}(\hat{A})$ is an overapproximation of the unknown lfp $f$ more precise than $\hat{A}$.
- However, this downward iteration $\left\langle Y^{n}, n \in \mathbb{N}\right\rangle$ might be infinite or converging slowly.
- It is therefore necessary to ensure its fast convergence. Convergence acceleration means that $Y^{n+1}$ will be a function of $Y^{n}$ and $f\left(Y^{n}\right)^{10}$ and so $Y^{n+1}=Y^{n} \Delta f\left(Y^{n}\right)$ where $\Delta$ is called a narrowing ${ }^{11}$.

[^4]
## Soundness

- For soundness, the narrowing must perform over-approximations, that is $y \sqsubseteq x \Delta y$, so as to stay above the unknown least fixpoint, which requires remaining above any fixpoint (which we have no way to distinguish from the least one) ${ }^{12}$.

[^5]
## Convergence

- For convergence, the narrowing must ensure termination with a fixpoint.

## Example: Interval Narrowing

For example, a narrowing for intervals could be

$$
\begin{aligned}
\emptyset \Delta y & \triangleq \emptyset \\
x \Delta \emptyset & \triangleq \emptyset \\
{[a, b] \Delta[c, d] } & \triangleq[(a=-\infty \text { ร } c: a),(b=+\infty \text { ร } d: b)]
\end{aligned}
$$

Recall than in $x \Delta y$ the $x$ is an iterate and $y$ is the next iterate $f(x)$. So [a, $b] \Delta[c, d]$ will just eliminate the infinite bounds in $[a, b]$ and replace them by the bounds of the next iterate $[c, d]$.

So the narrowed interval is larger than $[c, d]$ that is $f(x)$ which ensures that we perform an overapproximation. Because only finitely many bounds can be infinite hence potentially removed, termination is guaranteed.

## Example: Interval Narrowing (Cont'd)

## Encoding the Interval Narrowing

A functional encoding in of the narrowing in OCAML could be

```
(* interval narrowing *)
open Interval
let narrow x y = match x,y with
| EMPTY, _ -> EMPTY
| _, EMPTY -> EMPTY
| INT (a,b), INT (c,d) ->
    let a' = if a=min_int then c else a in
        let b' = if b=max_int then d else b in
            INT (a', b');;
```

## Invariant Narrowing

$P \triangleq{ }^{1} \mathrm{x}:=1 ;$ while ${ }^{2}$ true do ${ }^{3} \mathrm{x}:=(\mathrm{x}+1)$; od ${ }^{4}$.

In our example, the narrowing is applied once around the loop at program point 2 , like the widening.
(* invariantNarrowing.ml, invariant narrowing *) open IntervalNarrowing
let pnarrow (x1, x2, x3, x4) ( $x^{\prime} 1, x^{\prime} 2, x^{\prime} 3, x^{\prime} 4$ ) = ( $x^{\prime} 1$, narrow $x 2 x^{\prime} 2, x^{\prime} 3, x^{\prime} 4$ ); ;

## Abstract Interpreter with Widening/Narrowing

The abstract interpreter now calls the iterator using the invariant widening until reaching a postfixpoint and then calls the iterator using the invariant narrowing until reaching a fixpoint.

```
(* reachability analysis with widening and narrowing *)
open Invariant
open InvariantWidening
open InvariantNarrowing
open TransformerBounded
open Iterator
let analyzer () =
    let fw x = pwiden x (f x) in
        let w = (lfp pless pbot fw) in
        let fn x = pnarrow x (f x) in
        pprint (lfp pgreater w fn);;
analyzer (); ;
```

## Example of convergence acceleration by widening/narrowing

The result is now almost instantaneous.

```
% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml \
? invariant.ml invariantWidening.ml invariantNarrowing.ml \
? transformerBounded.ml iterator.ml \
? reachability_narrowing_bounded.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io Opf+0w
%
```

## Details of the iteration with Narrowing/Widening

When compared to the Jacobi iterations, the chaotic iterates with widening and narrowing are extremely fast as shown below.

```
% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml
? invariant.ml invariantWidening.ml invariantNarrowing.ml \
? transformerBounded.ml iteratorTrace.ml \
? reachability_narrowing_bounded_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,1) 4:_ l_
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,100) 4:(101,107374182\beta)
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,1073741823) 3:(1,100) 4:(101, 107374182\beta)
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,1073741823)
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## On the (im)precision of the analysis...

Of course the narrowing cannot always recover all information lost by the widening, in particular because it is blocked by fixpoints jumped over by the widening.

## Widening/Narrowing are not duals

So we need four different notations, as follows.

|  |  | Iteration <br> starts from | Iteration <br> stabilizes |
| ---: | :---: | :---: | :---: |
| Widening | $\nabla$ | below | above |
| Narrowing | $\Delta$ | above | above |
| Dual widening | $\widetilde{\nabla}$ | above | below |
| Dual narrowing | $\widetilde{\Delta}$ | below | below |

No dual widening $\widetilde{\nabla}$ has ever been found but trivial ones such as bounded execution (bounded model-checking), execution on a few cases (debugging), etc.

## On actual abstract interpreters

Remark 3.1 For simplicity, we have designed a specific abstract interpreter for a specific program.

- In practice, abstract interpreters are parameterized by the program they have to analyze, and by the abstraction which should be used for the analysis.

## On actual abstract interpreters

Remark 3.1 For simplicity, we have designed a specific abstract interpreter for a specific program.

- In practice, abstract interpreters are parameterized by the program they have to analyze, and by the abstraction which should be used for the analysis.
- Observe that the code defining the transformer could be directly generated from the program text and so we have a model of an abstract compiler.
- (An alternative would use a computer representation of the equations and an abstract interpreter would be used to evaluate the transformer by calls to the interval abstract domain).

# Chaotic Iterations: A Structural Instance 

## Chaotic iterations

the iteration of the abstract equations need not follow the Jacobi iteration strategy and can be done in any chaotic order provided no equation is forgotten forever (or equivalently every equation is evaluated infinitely often) until it is stabilized.

A particular instance of such an efficient chaotic iteration follows program execution as defined by induction on its syntax

Starting from the entry condition at program point ${ }^{1}$, we can stabilize the loop ${ }^{2}-{ }^{3}$ before computing the invariant at program point ${ }^{4}$.

## Structural iterations

```
(* structural reachability analysis with widening and
    narrowing *)
open Interval
open IntervalWidening
open IntervalNarrowing
open Invariant
open TransformerBounded
open Iterator
let analyzer () =
    let \(\mathrm{p} 1=\mathrm{f} 1\) () in
    let \(p 2=\) let \(f x 2=f 2 p 1(f 3 \mathrm{x} 2)\) in
        let \(f w x 2=\) widen \(x 2(f x 2)\) in
        let \(w=(l f p\) less EMPTY fo) in
        let \(f n \times 2=\) narrow \(x 2(f x 2)\) in
        (lap greater \(w f n\) ) in
        let ph \(=\mathrm{f} 3 \mathrm{p} 2\) in
        let \(\mathrm{p} 4=\mathrm{f} 4 \mathrm{p} 2\) in
        print (pi, ph, pB, p4);
analyzer (); ;
```

## Structural iterations (cont’d)

and get exactly the same global result (the trace shows the iteration with widening and then the iteration with narrowing for the loop ${ }^{2}-{ }^{3}$ )

```
% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml
? invariant.ml invariantWidening.ml invariantNarrowing.ml \
? transformerBounded.ml iteratorTrace.ml \
? structural_reachability_narrowing_bounded_trace.ml
% time ./a.out

0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io Opf+0w
%
```

## Verification

## Verifier

- The abstract interpreter that we have designed is a sound static analyzer. Given a program it produces interval information always valid at runtime.
- We can turn it into a verifier checking an interval specification.

## Verifier

- The abstract interpreter that we have designed is a sound static analyzer. Given a program it produces interval information always valid at runtime.
- We can turn it into a verifier checking an interval specification.
- The specification can be provided by the user or remain implicit (e.g. absence of runtime errors such as overflows).
- One kind of user specification is a type declaration, for example an interval declaration for integer variables like var x: 1..100;

## Verifier

- The abstract interpreter that we have designed is a sound static analyzer. Given a program it produces interval information always valid at runtime.
- We can turn it into a verifier checking an interval specification.
- The specification can be provided by the user or remain implicit (e.g. absence of runtime errors such as overflows).
- One kind of user specification is a type declaration, for example an interval declaration for integer variables like var x: 1..100; .
- Let us understand this declaration as: "only values between 1 and 100 can be assigned to x , otherwise execution stops" (with a runtime error).
- Observe that this does not mean that $x$ always has a value betwwen 1 and 100 because it can be initialized with any integer value. ${ }^{13}$.

[^6]

[^7]
## Example of Interval Verification

For the following example

$$
P^{\prime} \triangleq \operatorname{var} \mathrm{x}: 1 . .100 ;{ }^{1} \mathrm{x}:=1 ; \operatorname{while}^{2}(\mathrm{x}<=100) \text { do }^{3} \mathrm{x}:=(\mathrm{x}+1) ; \mathrm{od}^{4} .
$$

the abstract interval equations become

$$
\left\{\begin{aligned}
X_{1}= & \{\mathrm{x} \leftarrow[\text { min_int, max_int }]\} \\
X_{2}= & \left\{\mathrm { x } \leftarrow \left([ 1 , 1 ] \sqcup \left(X_{3}(\mathrm{x})=\emptyset \text { ? } \emptyset: \text { let }[a, b]=X_{3}(\mathrm{x})\right.\right.\right. \text { in } \\
& \left.\left.\quad\left[\min \left(a+1, \max _{-} \text {int }\right), \min \left(b+1, \max _{\_} \text {int }\right)\right]\right) \sqcap[1,100]\right\} \\
X_{3}= & X_{2} \dot{\Pi}\{\mathrm{x} \leftarrow[\text { min_int, } 100]\} \\
X_{4}= & X_{2} \dot{\Pi}\{\mathrm{x} \leftarrow[101, \text { max_int }]\}
\end{aligned}\right.
$$

since execution stops if and when a value outside [1, 100] is going to be assigned to x . The result of the analysis is now the following. This declaration

## Encoding the Declaration

This declaration is encoded in OCAML as follows

```
(* declaration.ml *)
open Interval
open Invariant
let d =
    (INT (min_int,max_int),
        INT (1,100),
        INT (min_int,max_int),
        INT (min_int,max_int)); ;
```

## Encoding the Verification Phase

The verification of absence of errors checks that at any point during an execution without error up to some point in the computation will not have an error at the next execution step.

```
(* verifier.ml, interval invariant abstract domain *)
let pwarning (b1, b2, b3, b4) =
    let m = "Potential error at line " in
    if not b1 then print_string (m^"1\n");
    if not b2 then print_string (m^"2\n");
    if not b3 then print_string (m~"3\n");
    if not b4 then print_string (m~"4\n");;
let pverify leq f a d =
    let b = leq (f a) d in
        pwarning b;
```

## Encoding the Verifier

The abstract interpreter performs the iterative abstract reachability fixpoint overapproximation with widening/narrowing and intersection with the declaration, then prints the least fixpoint result, and finally checks for errors.

```
(* reachability verification with widening and narrowing
open Invariant
open InvariantWidening
open InvariantNarrowing
open TransformerBounded
open Iterator
open Declaration
open Verifier
let verifier () =
    let fw x = (pmeet (pwiden x (f x)) d) in
        let w = (lfp pless pbot fw) in
            let fn x = pnarrow x (f x) in
            let a = (lfp pgreater w fn) in
                    pprint a; pverify cless f a d;;
verifier ();;
```

## Result of the Analysis

```
% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml \
? invariant.ml invariantWidening.ml invariantNarrowing.ml \
? transformerBounded.ml iterator.ml declaration.ml \
? verifier.ml reachability_narrowing_declaration.ml
% time ./a.out
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,100) 4:_l_
Potential error at line 2
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

- Observe that the program execution always stops at program point ${ }^{3}$ with an overflow outside the range $[1,100]$ so program point ${ }^{4}$ is now unreachable (with an overapproximation we can prove the presence of dead code but not its absence).
- Notice that the error is signaled as potential (with an overapproximation we can prove the values to definitely be within given bounds but not to prove that execution ever assigns a given value to a variable). Here is a trace of the analysis.

## Details of the Analysis

```
% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml \
? invariant.ml invariantWidening.ml invariantNarrowing.ml \
? transformerBounded.ml iteratorTrace.ml declaration.ml\
? verifier.ml reachability_narrowing_declaration_trace.ml
% time ./a.out
    1:_l_ 2:_l_ 3:_l_ 4:_l_
    1:(-1073741824,1073741823) 2:(1,1) 3:_ l_ 4:_ |_
    1:(-1073741824,1073741823) 2:(1,1) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,1) 4:_l_
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,100) 4:_l_
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,100) 4:_l_
    converged to lfp.
    1:(-1073741824,1073741823) 2:(1,100) 3:(1,100) 4:_l_
Potential error at line 2
0.000u 0.000s 0:00.00 0.0% 0+0k 0+0io 0pf+0w
%
```

## Correcting the Declaration

```
(* declarationCorrect.ml *)
open Interval
open Invariant
let d =
    (INT (min_int,max_int),
    INT (1,101),
    INT (min_int,max_int),
    INT (min_int,max_int)); ;
```

yields no error, the verification is completed.

```
\% ocamlc interval.ml intervalWidening.ml intervalNarrowing.ml \}
? invariant.ml invariantWidening.ml invariantNarrowing.ml \}
? transformerBounded.ml iterator.ml declarationCorrect.ml \}
? verifier.ml reachability_narrowing_declaration_correct.ml
\% time ./a.out
    1:(-1073741824,1073741823) 2:(1,101) 3:(1,100) 4:(101,101)
\(0.000 \mathrm{u} 0.000 \mathrm{~s} 0: 00.00\) 0.0\% 0+0k 0+0io 0pf+0w
\%
```

## When to do the verification?

Notice that in general the verification cannot be done during the analysis since a widening may cause an overapproximation potentially raising a potential error while the narrowing may refine the analysis well enough to that this potential error disappears.

## Abstract Interpreters

- Transitional abstract interpreters: proceed by induction on program steps
- Structural abstract interpreters: proceed by induction on the program syntax
- Common main problem: over/under-approximate fixpoints in non-Noetherian(*) abstract domains (**)
(*) Iterative fixpoint computations may not converge in finitely many steps
$\left.{ }^{* *}\right)$ Or convergence may be guaranteed but to slow.

## Fixpoint Iteration

Convergence Acceleration by Extrapolation and Interpolation

[^8]
## Fixpoints

- Poset (or pre-order) <D, ᄃ, $\perp, \sqcup>$
- Transformer: $\mathrm{F} \in \mathrm{D} \longmapsto \mathrm{D}$
- Least fixpoint: lfp ${ }^{\sqsubseteq} F=\bigsqcup_{n \in \mathbb{N}} F^{n}(\perp)$ (under appropriate hypotheses)

## Convergence acceleration with widening

Infinite iteration

## Convergence acceleration with widening

Infinite iteration
Accelerated iteration with widening (e.g. with a widening based on the derivative as in Newton-Raphson method ${ }^{(*)}$ )
(*) Javier Esparza, Stefan Kiefer, Michael Luttenberger: Newtonian program analysis. J. ACM 57(6): 33 (2010)

## Extrapolation by Widening

- $X^{0}=\perp$ widening)
$X^{n+1}=X^{n} \nabla F\left(X^{n}\right)$
$X^{n+1}=X^{n}$
- Widening $\nabla$ :
(increasing iterates with
when $F\left(X^{n}\right) \nsubseteq X^{n}$
when $F\left(X^{n}\right) \sqsubseteq X^{n}$
- $Y \sqsubseteq X \nabla Y$
(extrapolation)
- Enforces convergence of increasing iterates with widening (to a limit $\mathrm{X}^{t}$ )

## The oldest widenings

## - Primitive widening [1,2]

$$
\begin{aligned}
& {\left[a_{1}, b_{1}\right] \bar{\nabla}\left[a_{2}, b_{2}\right]=} \\
& \quad \text { [if } a_{2}<a_{1} \text { then }{ }^{-\infty} \text { else } a_{1} \text { fi },
\end{aligned}
$$

$$
\text { if } b_{2}>b_{1} \text { then }+\infty \text { else } b_{1} \text { fi] }
$$

- Widening with thresholds [3]

$$
\begin{aligned}
& \forall x \in \bar{L}_{2}, \perp \nabla_{2}(j) x=x \nabla_{2}(j) \perp=x \\
& {\left[l_{1}, u_{1}\right] \nabla_{2}(j)\left[l_{2}, u_{2}\right]} \\
& =\quad\left[\text { if } 0 \leq l_{2}<l_{1} \text { then } 0 \text { elsif } l_{2}<l_{1} \text { then }-b-1 \text { else } l_{1} f,\right. \\
& \left.\quad \text { if } u_{1}<u_{2} \leq 0 \text { then } 0 \text { elsif } u_{1}<u_{2} \text { then } b \text { else } u_{1} f i\right]
\end{aligned}
$$

[^9]
## Extrapolation with widening

## Interpolation with narrowing

- $Y^{0}=X^{e}$
narrowing)
$Y^{n+1}=Y^{n} \Delta F\left(Y^{n}\right)$
$Y^{n+1}=Y^{n}$
(decreasing iterates with
when $F\left(Y^{n}\right) \sqsubset Y^{n}$
when $F\left(Y^{n}\right)=Y^{n}$
- Narrowing $\Delta$ :
- $Y \sqsubseteq X \Longrightarrow Y \sqsubseteq X \Delta Y \sqsubseteq X$
(interpolation)
- Enforces convergence of decreasing iterates with narrowing (to a limit $Y^{\lambda}$ )

## The oldest narrowing

[2]

$$
\begin{aligned}
& {\left[a_{1}, b_{1}\right] \bar{\Delta}\left[a_{2}, b_{2}\right]=} \\
& {\left[\underline{\text { if } a_{1}}=-\infty \text { then } a_{2} \text { else } \operatorname{MIN}\left(a_{1}, a_{2}\right),\right.} \\
& \left.\underline{\text { if } b_{1}=+\infty} \text { then } b_{2} \text { else } \operatorname{MAX}\left(b_{1}, b_{2}\right)\right]
\end{aligned}
$$

## Interpolation with narrowing

Could stop when $F(X) \nsubseteq X \wedge F(F(X)) \sqsubseteq F(X)$ but not the current practice.

## Duality

|  | Convergence above the limit | Convergence below the limit |
| :--- | :---: | :---: |
| Increasing iteration | Widening $\nabla$ | Dual-narrowing $\widetilde{\triangle}$ |
| Decreasing iteration | Narrowing $\triangle$ | Dual widening $\widetilde{\nabla}$ |

Extrapolators $(\nabla, \widetilde{\nabla})$ and interpolators $(\Delta, \widetilde{\Delta})$

- Extrapolators:

- Interpolators:

## Extrapolators, Interpolators, and Duals

## Interpolation with dual narrowing

- $Z^{0}=\perp \quad$ (increasing iterates with dual-narrowing)
$Z^{n+1}=F\left(Z^{n}\right) \tilde{\Delta} Y^{\lambda} \quad$ when $F\left(Z^{n}\right) \nsubseteq Z^{n}$
$Z^{n+1}=Z^{n} \quad$ when $F\left(Z^{n}\right) \sqsubseteq Z^{n}$
- Dual-narrowing $\widetilde{\Delta}$ :
- $X \sqsubseteq Y \Rightarrow X \sqsubseteq X \widetilde{\Delta} Y \sqsubseteq Y$
(interpolation)
- Enforces convergence of increasing iterates with dual-narrowing

## Example of dual-narrowing

$$
[a, b] \widetilde{\Delta}[c, d] \triangleq[\lfloor c=-\infty \text { ว } a \circ\lfloor(a+c) / 2\rfloor\rceil,\lceil d=\infty \text { ว } b:\lceil(b+d) / 2\rceil)]
$$

- The first method we tried in the late 70's with Radhia
- Slow
- Does not easily generalize (e.g. to polyhedra)

## Interpolation with dual-narrowing

## Relationship between narrowing and dual-

- $\Delta=\Delta^{-1}$
- $Y \sqsubseteq X \Longrightarrow Y \sqsubseteq X \Delta Y \sqsubseteq X$
(narrowing)
- $\mathrm{Y} \sqsubseteq \mathrm{X} \Rightarrow \mathrm{Y} \sqsubseteq \mathrm{Y} \Delta \mathrm{X} \mathrm{X}$
(dualnarrowing)
- Example: Craig interpolation
- Why not use a bounded widening (bounded by $B$ )?
- $\mathrm{F}(\mathrm{X}) \sqsubseteq \mathrm{B} \Longrightarrow \mathrm{F}(\mathrm{X}) \sqsubseteq \mathrm{F}(\mathrm{X}) \Delta \mathrm{B} \sqsubseteq \mathrm{B} \quad$ (dualnarrowing)

## Example of widenings (cont'd)

- Bounded widening (in $[\ell, h]$ ):

$$
[a, b] \nabla_{[\ell, h]}[c, d] \triangleq \frac{[c+a-2 l}{2}, \frac{b+d+2 h]}{2}
$$

## Widenings

## Widenings are not increasing

- A well-known fact
$[1,1] \subseteq[1,2]$ but $[1,1] \nabla[1,2]=[1, \infty] \nsubseteq[1,2] \nabla[1,2]=[1,2]$
- A widening cannot both:
- Be increasing in its first parameter
- Enforce termination of the iterates
- Avoid useless over-approximations as soon as a solution is found ${ }^{(*)}$
${ }^{\text {(*) }}$ A counter-example is $x \nabla y=T$

## Soundness

## Soundness

- The fixpoint approximation soundness theorems cab expressed with minimalist hypotheses ${ }^{[1]}$ :
- No need for complete lattices, complete partial orders (CPO's):
- The concrete domain is a poset
- The abstract domain is a pre-order
- The concretization is defined for the abstract iterates only.

## Soundness (cont'd)

- No need for increasingness/monotony hypotheses for fixpoint theorems (Tarski, Kleene, etc)
- The concrete transformer is increasing and the limit of the iterations does exist in the concrete domain
- No hypotheses on the abstract transformer (no need for fixpoints in the abstract)
- Soundness hypotheses on the extrapolators/ interpolators with respect to the concrete
- In addition, termination hypotheses on the extrapolators/interpolators ensure convergence in finitely many steps

## Soundness (cont'd)

- No need for increasingness/monotony hypotheses for fixpoint theorems (Tarski, Kleene, etc)
- The concrete transformer is increasing and the limit of the iterations does exist in the concrete domain
- No hypotheses on the abstract transformer (no need for fixpoints in the abstract)
- Soundness hypotheses on the extrapolators/ interpolators with respect to the concrete

## Examples of interpolators

## Craig interpolation

Craig interpolation:

$$
\begin{aligned}
& \text { Given } \mathrm{P} \Longrightarrow \mathrm{Q} \text { find } \mathrm{I} \text { such that } \mathrm{P} \Longrightarrow \mathrm{I} \Longrightarrow \mathrm{Q} \text { with } \\
& \operatorname{var}(\mathrm{I}) \subseteq \operatorname{var}(\mathrm{P}) \cap \operatorname{var}(\mathrm{Q})
\end{aligned}
$$

is a dual narrowing (already observed by Vijay D'Silva and Leopold Haller as an inversed narrowing)

## Craig interpolation

Craig interpolation:

$$
\begin{aligned}
& \text { Given } \mathrm{P} \Longrightarrow \mathrm{Q} \text { find } \mathrm{I} \text { such that } \mathrm{P} \Longrightarrow \mathrm{I} \Longrightarrow \mathrm{Q} \text { with } \\
& \operatorname{var}(\mathrm{I}) \subseteq \operatorname{var}(\mathrm{P}) \cap \operatorname{var}(\mathrm{Q})
\end{aligned}
$$

is a dual narrowing (already observed by Vijay D'Silva and Leopold Haller as an inversed narrowing)

## Craig interpolation

Craig interpolation:

> Given $P \Longrightarrow Q$ find $I$ such that $P \Longrightarrow I \Longrightarrow Q$ with $\operatorname{var}(\mathrm{I}) \subseteq \operatorname{var}(\mathrm{P}) \cap \operatorname{var}(\mathrm{Q})$
is a dual narrowing

## Conclusion

## Conclusion \& references

## Conclusion

- The presentation relied purely on intuition, can be made formal (see references)
- The abstraction ideas can scale up with enough precision, e.g.

[^0]:    ${ }^{1}$ by Tarski fixpoint theorem

[^1]:    ${ }^{2}$ e.g. in two's complement representation on 64 bits, we have generally have min_int $=$ -2147483648 and max_int $=2147483647$.
    ${ }^{3}$ Which is a rather simplifying hypothesis since most computers will go on providing a result modulo max_int so that e.g. max_int $+1=$ min_int in two's complement representation.

[^2]:    ${ }^{7}$ The justification is again by Tarski

[^3]:    ${ }^{7}$ The justification is again by Tarski since $f(\hat{A}) \sqsubseteq \hat{A}$ implies $\operatorname{Ifp} f \sqsubseteq \hat{A}$.
    ${ }^{8}$ and more generally $X^{n+1}$ could depend on the sequence of previous iterates $X^{0}, f\left(X^{0}\right), \ldots$, $X^{n}, f\left(X^{n}\right)$, but we can use a reencoding to prove that a proof by strong induction can always be done by a weak recurrence and inversely.
    ${ }^{9}$ We use a binary operator notation rather than a functional notation because of the analogy between widenings $\nabla$ and joins $\vee$, $\sqcup$, etc,

[^4]:    ${ }^{10}$ and more generally $Y^{n+1}$ could depend on the sequence of previous iterates $Y^{0}, f\left(Y^{0}\right), \ldots$, $Y^{n}, f\left(Y^{n}\right)$, as was also the case for widening.
    ${ }^{11}$ We use a binary operator notation rather than a functional notation because of the analogy between narrowing $\Delta$ and meets $\wedge, \Pi$, etc

[^5]:    ${ }^{12} \mathrm{By}$ recurrence, if $X=f(X)$ is any fixpoint of $f$ such that $X \sqsubseteq Y^{n}$ then $X=f(X) \sqsubseteq f\left(Y^{n}\right)$ since $f$ is increasing so $X \sqsubseteq Y^{n} \sqsubseteq Y^{n} \Delta f\left(Y^{n}\right)=Y^{n+1}$ by the overapproximation hypothesis.
